

ASSIGNMENT 4

1) KPI card — “Sum of Hospital overall rating” = 11K

Sum of Hospital Overall Rating

- The large "11K" figure represents the total sum of hospital overall ratings accrued in this dataset.
- This aggregate rating highlights the combined score from all hospitals, which can be used to assess total surveyed performance in a given period.
- Insight: A higher sum may indicate numerous participating hospitals or generally high ratings across the dataset.

2) Slicer / Filter list under KPI — Patient experience / State rows (Above the n..., Below the n..., Not Available; AK, AL, ...)

- What it is: A slicer showing categories (Patient experience national comparison) for top 5 states

3) Gauge — “Count of Mortality national comparison” (3546, scale 0 → 7092)

- What it is: A gauge measuring the count (or aggregated count) of mortality records that fall in the current scope/filters. The center shows 3,546; scale maximum is 7,092.
- How to read: The needle/arc position and central number tell you where current mortality count sits relative to the maximum in the dataset. If the arc is red/green, it can also indicate target vs actual.
- Insight: If 3,546 is ~50% of max, mortality is substantial; combine with map/hospital-level charts to see which hospitals/states are contributing most to mortality.

4) Map — “State and Effectiveness of care national comparison” (choropleth / categorical map)

- What it is: A U.S. map showing each state colored by the “Effectiveness of care national comparison” category (legend shows colors for “Above the national...”, “Below the...”, “Not Available”).
- How to read: Each color corresponds to a category; darker/lighter hues or distinct colors indicate whether the state’s aggregated effectiveness is above, below, or unavailable versus the national benchmark. Hovering a state in the actual report would show tooltip details (counts, averages).
- Insight examples: Regions with many “Above the national” states (dominant color) indicate consistently better outcomes; pockets of “Below” or “Not Available” identify targets for investigation. Clicking a state will filter other charts to that state.

5) Bar chart (top-right) — “Count of Mortality national comparison by Hospital Name and Hospital Type”

Count of Mortality National Comparison & Hospital Type by Name

- The semicircular gauge shows 3546 hospitals involved in national mortality comparisons, out of a total of 7092 possible hospitals.
- This is roughly 50% participation, suggesting moderate engagement in mortality performance reporting.
- The horizontal bar chart visualizes counts of hospitals by type/name, with "MEMOR..." leading, then "GOOD..." and "ST JOSE...".
- Insight: Some hospital chains/networks dominate in certain metrics, indicating concentration of services or reporting within those groups

6) Line chart (small, top-right) — “Sum of Hospital overall rating by Timeliness of care ...”

- What it is: A trend/line chart plotting the sum of overall hospital ratings across categories of “Timeliness of care national comparison” (categories along the x-axis: “Same as...”, “Above the...”, “Below th...”, “Not Avail...”). The y-axis shows sum values (scale shows from 0K up to 5K).
- How to read: The line’s slope shows how total rating varies across timeliness categories. In the screenshot the line trends downward from left to right — meaning the sum of overall ratings is

higher in the left-most timeliness category and lower in the right-most.

- Insight: If “Same as the national...” (left) has the highest sum, while “Below the national...” is lower, that suggests timeliness is correlated with overall rating. Use this to prioritize initiatives to improve timeliness.

7) Stacked column chart (middle-right) — “Sum of Hospital overall rating by Patient experience national comparison and Hospital Name”

- What it is: Clustered columns representing patient-experience categories (grouped by categories: “Above the national...”, “Same as the national...”, “Below the national ...”, “Not Available”). Each column is subdivided (stacked) by Hospital Name (legend shows many hospital names as colors).
- How to read: For each patient-experience category, the total column height = total of hospital overall ratings across all hospitals; each colored slice shows that hospital’s contribution.
- Observations / caveats: Because Hospital Name is used as the stack legend, this visual becomes highly colorful and hard to read when many hospitals are present — the individual hospital slices will be tiny. Use it to see category-level totals and which hospitals are non-trivial contributors (visible larger slices).
- Insight: Compare total rating across patient-experience categories: e.g., is the total rating much larger in “Above the national” vs “Below the national”? If yes, patient experience tracks overall rating strongly.

8) Donut chart — “Sum of Hospital overall rating by Hospital Ownership”

- What it is: Donut (pie) showing how the sum of overall ratings is distributed by hospital ownership type (legend shows categories such as Voluntary, Proprietary, Government, etc.). The slices are annotated with rough totals and percentages (example visible: 5K = 46.19%, 2K = 15.94%, 1K = 9.03%, etc.).
- How to read: Each slice’s size and percent show what share of the total rating sum comes from that ownership type. The numeric labels on slices (5K, 2K, 1K) give absolute contribution.
- Insight: Ownership types that contribute nearly half of the total (46.19% here) are dominant. If one ownership type has both a high share and poor performance on other metrics (e.g., high mortality), that flags a structural issue to investigate by ownership model.

9) Vertical bar chart (bottom-left) — “Count of Hospital Type by Hospital Name”

- What it is: Simple vertical bar chart showing counts of hospitals by hospital type for top hospital names (labels truncated: MEMOR..., GOOD..., ST JOSE...). Y-axis = count (0–10 shown). Bars are colored (blue) likely indicating a single type selected or default color palette.

- How to read: Each bar tells how many hospitals (or how many records of that hospital type) correspond to that Hospital Name. If the hospital name repeats for different types, you'll see separate bars (or a stacked variant).
- Insight: Quickly identifies the most common hospital names in the dataset or which hospitals have the most records. Useful to cross-check whether a few hospitals dominate counts.

10) Horizontal stacked bar (bottom-right) — “Count of State by Hospital Name and Timeliness of care national comparison”

- What it is: Horizontal stacked bars: Y-axis = Hospital Name (several hospitals listed), X-axis = Count of State (number of states represented for that hospital or count of records aggregated by state), and stacks show timeliness categories (legend colors: Above the national avg, Below the national, Not Available, Same as the national).
- How to read: For each hospital row, the entire horizontal bar length = total count (states or records). Different colored segments show how that total breaks down by timeliness category. E.g., Memorial Hospital has large purple segment (likely “Same as the national...”) plus blue for “Above...”.
- Insight: This is great to compare hospitals on timeliness mix. A hospital with a large segment in “Below the national” is a candidate for operational improvement; a hospital with mostly “Above” or “Same as” is comparatively timely.
